Version 1.0 · 2026

Wyoming-Incorporated · Reg D 506(c) · Confidential

Built by operators who scaled \$0 → \$5B AUM

Executive Summary

DeedRiver is a global real estate tokenization platform — a three-layer infrastructure that converts income-producing real estate into compliant on-chain assets, enables institutional-grade yield distribution, and provides regulated secondary transfer for accredited participants. The platform unifies three traditionally fragmented capabilities — asset tokenization, AI-driven intelligence, and decentralized exchange — into a single operational stack.

The category is reaching an inflection point. Tokenized real-world assets grew approximately 380% to over \$24 billion in 2025, making it the fastest-growing crypto sector after stablecoins. Within that segment, tokenized Treasuries already account for roughly \$7.5 billion in on-chain assets. Tokenized real estate, by contrast, stands at approximately \$250 million — a fraction of its eventual addressable share. The Boston Consulting Group projects the tokenized real estate market alone will reach \$5 trillion by 2030, against a \$350 trillion global real estate asset class. This asymmetry — institutional infrastructure built out, real estate barely on the curve — is the opportunity DeedRiver is positioned to capture.

Regulatory clarity is arriving in parallel. The CLARITY Act cleared the Senate Banking Committee 15-9 on May 14, 2026; the GENIUS Act became the first federal stablecoin framework in July 2025; Wyoming's digital asset statutes and DAO LLC framework remain the strongest tokenization-favorable jurisdiction in the United States. Globally, MiCA is fully applicable in the European Union, the United Arab Emirates' VARA framework is operational with active real estate tokenization pilots, and Hong Kong has published a ten-year RWA roadmap. The institutional players — BlackRock, JPMorgan, Fidelity, Apollo, KKR — are already on-chain. The 18-30 month window before they dominate the real estate vertical is the urgency premise of this whitepaper.

This is a fintech problem disguised as a blockchain problem. Whoever moves first becomes the acquisition target.

DeedRiver's strategic position rests on four pillars. First, the comprehensive platform — tokenization, AI intelligence, and DEX marketplace as one integrated stack rather than the fragmented vendor-by-vendor approach that has defined the category to date. Second, the YieldDeed wedge application — a non-recourse home equity tokenization product for luxury homeowners that generates origination, asset-management, and rental-skim revenue from day one without depending on secondary market liquidity. Third, the AI-driven back-office accounting and compliance layer — the operational moat that makes per-property unit economics viable at any scale and that incumbent tokenization platforms have not built. Fourth, the team — led by a CTO who has already scaled an institutional fund platform from zero to \$5 billion in assets under management.

This whitepaper details the operational reality of tokenized real estate, the technical architecture of DeedRiver's automation layer, the phased go-to-market that begins with development projects and luxury homes today and expands to institutional single-family portfolios as regulatory clarity matures, and the competitive landscape across both consumer financial products and existing tokenization platforms. The document is intended for diligence audiences — investors, technical advisors, regulatory counsel, and strategic acquirers — who need depth beyond what a pitch deck provides.

S E C T I O N 1

The Real Estate Tokenization Opportunity

A broken asset class

Real estate is the world's largest asset class — approximately \$350 trillion globally — and the most operationally broken. Four structural problems define the category as it exists today, and each maps directly to a corresponding capability in tokenization infrastructure.

Illiquidity

Private capital markets raise approximately \$2.9 trillion annually but trade only \$0.1 trillion — roughly 330 times less liquid than public markets, which raise \$1.4 trillion and trade \$33 trillion. Real estate, as the largest single component of private capital, inherits this asymmetry in its most extreme form. Institutional real estate funds typically lock investor capital for seven to ten years. Property developers face capital formation cycles of eighteen to twenty-four months, targeting a small universe of ultra-high-net-worth buyers because the secondary market for fractional interests does not exist.

Inefficiency

Global clearing and settlement infrastructure imposes approximately \$54 billion in annual costs across capital markets, with real estate contributing a disproportionate share due to its dependence on title transfer, escrow, notarization, and multi-party legal coordination. Standard real estate transactions take six to twelve months to clear. Even when the underlying buyer-seller agreement is reached in days, the operational tail — title search, lender coordination, recording, tax clearance, closing — adds months of friction. This is the friction that smart contracts and tokenized title structures are designed to eliminate.

Inaccessibility

Approximately 93% of institutional-grade real estate remains inaccessible to retail investors. Direct participation typically requires \$1 million minimum investment, accreditation, and in many cases a personal relationship with the sponsor. The investor universe is structurally limited to family offices, RIAs, and a relatively small pool of UHNW individuals. The retail capital that flows freely into public equity markets — through brokerage accounts, robo-advisors, and ETF wrappers — has no clean counterpart in real estate.

Fragmentation

No integrated platform exists today that unifies the supply side of real estate (property acquisition, legal structuring, tokenization, capital formation) with the demand side (investor onboarding, fractional access, secondary liquidity, regulatory compliance). The existing tokenization platforms — Securitize, Tokeny, Polymath, Centrifuge, and others — are technology layers. They issue tokens but leave the operational stack to the issuer or sponsor. The existing real estate platforms — Roofstock, Fundrise, Cadre — are vertically integrated but not tokenization-native and lack the on-chain rails for secondary liquidity. DeedRiver is positioned in the gap between these categories.

The perfect storm

Three converging forces define the present moment as the inflection point for real estate tokenization.

Regulatory unlock

The clearest signal in a decade. The CLARITY Act — the Digital Asset Market Clarity Act of 2025 — cleared the Senate Banking Committee 15-9 on May 14, 2026, establishing the framework for jurisdictional clarity between the SEC and CFTC for digital assets. Final passage by year-end 2026 is realistic. The GENIUS Act, signed into law in July 2025, became the first federal stablecoin framework, providing the payments rail for tokenized asset settlement. Wyoming's digital asset statutes — including the DAO LLC entity framework and explicit recognition of tokenized property rights — remain the strongest tokenization-favorable jurisdiction in the United States and the operational home of DeedRiver's pilot.

Internationally, the European Union's Markets in Crypto-Assets Regulation (MiCA) has been fully applicable since December 30, 2024, with over ninety crypto-asset service providers authorized. The United Arab Emirates' Virtual Assets Regulatory Authority (VARA) has been operational since 2023, and Dubai's Land Department launched the region's first real estate tokenization pilot — selling out its initial offering in under two minutes — with a stated target of \$16 billion in tokenized real estate by 2033. Hong Kong's ten-year RWA tokenization roadmap, published in 2025, positions the territory as Asia's institutional tokenization hub. Singapore's Project Guardian, led by the Monetary Authority of Singapore, brings together UBS, Invesco, and Apollo on institutional tokenization pilots.

Institutional validation

The largest names in finance are now on-chain. BlackRock's BUIDL — a tokenized U.S. Treasury fund launched in March 2024 — peaked at approximately \$2.9 billion in assets under management by mid-2025, capturing over 40% of the tokenized Treasury market. JPMorgan launched its MONY tokenized money-market fund on Ethereum, seeded with \$100 million. Fidelity's FDIT tokenized Treasury fund surpassed \$250 million by December 2025. Apollo, KKR, and Hamilton Lane are actively tokenizing private market exposures through Securitize. Canton Network, backed by Goldman Sachs, Citadel Securities, and DTCC, now hosts more than \$6 trillion in tokenized assets across its institutional consortium.

The pattern is consistent: institutional infrastructure is being built and operationalized today, but the focus has been on the most liquid and least operationally complex asset classes — Treasuries, money-market funds, private credit. Real estate, with its greater operational complexity, has been left for later. This timing gap is the strategic opportunity.

Narrow window

The window for category capture is narrow. RWA tokenization grew approximately 380% to over \$24 billion in 2025, making it the fastest-growing crypto sector after stablecoins. The tokenized Treasury market reached approximately \$7.5 billion. Tokenized real estate, at approximately \$250 million, sits at the very beginning of its growth curve. The institutions that have already built tokenization infrastructure for Treasuries can pivot to real estate as soon as regulatory clarity and operational tooling mature — and the operational tooling is precisely the part DeedRiver is positioned to provide.

Sophisticated investors have noted the pattern. The institutional acquisition thesis — that early movers in regulated tokenization infrastructure are likely to be acquired by institutional players at significant multiples once the category matures — has historical precedent in adjacent categories. Goldman Sachs's

acquisition history in trading infrastructure, JPMorgan's acquisition of digital asset and tokenization startups, BlackRock's strategic stake in Securitize — these are not theoretical exits. They are the playbook.

Real estate tokenization sits at approximately \$250 million. Tokenized Treasuries are already at \$7.5 billion. The 18-30 month window before institutions close that gap is the opportunity.

S E C T I O N 2

The DeedRiver Platform

Three integrated layers

DeedRiver is structured as three integrated layers that operate as a single platform. The architecture choice is deliberate: each layer addresses one of the four structural problems described in Section 1, and the integration between them is the platform's primary competitive moat against the fragmented vendor-by-vendor approach that defines existing tokenization platforms.

Asset Layer — Tokenization Platform

The Asset Layer handles property digitization and DEED token minting. Each tokenized property is registered in a special-purpose vehicle — typically a Wyoming LLC or DAO LLC for U.S. assets, or a corresponding entity in partner jurisdictions for international assets. Tokens are issued as compliant securities under Reg D 506(c) for accredited domestic investors, with planned Reg A+ Tier 2 qualification for mass-affluent retail access. Smart contracts handle issuance, escrow, distribution mechanics, and ownership transfer. Multi-jurisdiction compliance modules support property tokenization across the United States, the United Arab Emirates, the European Union, Hong Kong, Singapore, and Malaysia, with additional jurisdictions added as partner relationships mature.

Intelligence Layer — AI

The Intelligence Layer is the connective tissue across the platform. Agentic AI systems handle deal sourcing and property qualification, automated KYC and AML verification, investor risk profiling and accreditation tracking, predictive valuation models, and — critically — the post-issuance accounting, tax, and compliance workflows that are the subject of Section 4 of this document. The Intelligence Layer is the operational engine that makes per-property unit economics work at any scale, replacing what would otherwise be tens of thousands of dollars per property in fragmented vendor costs.

Liquidity Layer — DEX Marketplace

The Liquidity Layer is the compliant secondary transfer infrastructure. Tokens trade peer-to-peer on the DeedRiver DEX, with real-time price discovery, automated eligibility checks, and institutional-grade custody integration. Transfers are subject to securities restrictions, accreditation verification, and jurisdiction-specific compliance — the marketplace is decentralized in its trading mechanics but permissioned in its participant access, consistent with regulated securities tokens. Platform fees are designed to be sub-1.5% per side, materially below the friction costs of traditional private market transfers.

Supply side and demand side

The platform serves two distinct customer populations that must be developed in parallel. Treating them as a single market — the failure mode of many tokenization platforms — obscures the operational realities of each side.

Supply side: where the assets come from

The supply side of the DeedRiver platform originates real estate assets into tokenized form. The initial supply categories include ground-up development projects (typically \$10 million to \$100 million in gross development value), luxury homes via the YieldDeed product, and — in subsequent phases — international development projects, institutional single-family rental portfolios, and commercial real estate. Each category has different operational characteristics, customer psychology, sales cycles, and unit economics.

The defining constraint on the supply side is the per-property operational stack. Each tokenized property requires entity formation, securities registration, ongoing compliance, distribution mechanics, K-1 generation, audit preparation, and secondary transfer infrastructure. The fixed costs of this stack determine the minimum viable property value at which tokenization is economically rational. Section 3 of this document provides the operational analysis; Section 4 explains the AI automation that compresses these costs.

Demand side: where the capital comes from

The demand side of the platform serves the investor population — initially accredited domestic investors under Reg D 506(c), expanding to mass-affluent retail under Reg A+ Tier 2, and ultimately institutional capital (pension funds, insurance companies, endowments, sovereign wealth) and international investors under partner-jurisdiction regulatory frameworks. Each investor class has different acquisition channels, ticket sizes, due diligence requirements, and operational support needs.

The chicken-and-egg problem familiar to two-sided marketplaces — that supply waits for demand and demand waits for supply — is solved on the DeedRiver platform by the YieldDeed wedge application and the DeedRiver Capital fund. YieldDeed generates revenue without requiring DEX secondary order flow, while the internal capital fund seeds initial demand-side liquidity for both YieldDeed and early Marketplace offerings.

The YieldDeed wedge application

YieldDeed is the platform's first specialization — a non-recourse home equity tokenization product designed for homeowners who want liquidity from their property without selling or taking on traditional debt. The strategic role of YieldDeed in the platform architecture is to generate origination revenue, asset-management fees, and rental income from day one, while the Marketplace, DEX, and broader platform mature. YieldDeed does not depend on secondary market order flow to be profitable. This decouples DeedRiver's early-stage revenue from the marketplace-liquidity chicken-and-egg problem that has killed previous tokenization platforms.

The product mechanics are straightforward. A homeowner's net equity in a qualifying property is tokenized into 1,000 DEED tokens representing 100% of the equity. The homeowner pledges 60% to 80% of those tokens to the DeedRiver Capital fund as non-recourse collateral. The fund advances capital against the pledged tokens, which is deployed into the fund's diversified yield-generating strategies (real estate operations, treasury management, additional tokenized properties). Returns distribute quarterly to the homeowner, net of fees. The deed itself never moves; title remains with the homeowner; the pledge is non-recourse, meaning the homeowner's liability is limited to the pledged tokens themselves, not personal credit.

YieldDeed generates origination, AUM, and rental-skim revenue from day one — no DEX order flow required.

YieldDeed is positioned for launch with luxury homes first. The unit-economics math is straightforward: per-property entity overhead — entity formation, registered agent, K-1 generation, custody, audit support, securities counsel review — runs approximately \$15,000 to \$40,000 in annual fixed costs. At luxury home values, the platform fees (origination plus asset management plus rental skim) materially exceed these fixed costs from year one. At sub-luxury values, the unit economics require either regulatory simplification (the post-CLARITY Act environment) or the AI accounting automation described in Section 4 — and ideally both. The phased go-to-market in Section 5 reflects this reality.

S E C T I O N 3

The Operational Reality of Tokenized Real Estate

This section addresses what most tokenization pitch decks omit: the operational stack that sits underneath every tokenized property and that determines whether the unit economics of the business actually work. The analysis here is the foundation of DeedRiver's competitive differentiation and the rationale for the AI accounting and compliance layer described in Section 4.

Per-property entity structure

Virtually every tokenized real estate offering in the United States today is structured as a special-purpose vehicle — typically a Series LLC, a Delaware Statutory Trust (DST), or a Wyoming LLC or DAO LLC — that holds the underlying real property and issues tokens representing fractional membership interests in the entity. This is not a stylistic choice. It is forced by four converging legal and operational realities.

Legal mechanics force it

Tokens must represent something legally cognizable. The underlying real property cannot be directly fractionalized at the deed level in most U.S. jurisdictions — real property law requires whole-asset transfer mechanisms (deeds, recorded title) that do not natively support fractional digital ownership. The token therefore must represent a fractional interest in an entity that holds the property, not the property itself. The entity is the legal bridge between the on-chain token and the off-chain asset.

Securities law forces it

Reg D 506(c) offerings — the predominant regulatory framework for tokenized real estate in the United States — require a defined issuer. That issuer must file Form D with the SEC, comply with state blue-sky requirements, maintain investor records, manage distributions, generate K-1s for pass-through tax treatment, and handle all corporate housekeeping. One issuer per property keeps liability, accounting, and audit trails clean. Combining multiple properties into a single issuer creates cross-property liability exposure that sophisticated investors will not accept.

Capital structure forces it

Real estate investors expect that a bad outcome on one property does not claim the assets of another. Per-property entities provide that isolation. Series LLCs partially address this by creating internal cells with statutory liability separation, but each cell still operates substantially as a separate entity for tokenization, accounting, and tax purposes.

Tax structure forces it

Pass-through tax treatment is essential for real estate. Investors expect to receive their proportional share of depreciation, expense deductions, and capital gains treatment. LLCs and DSTs preserve pass-through treatment. Lumping properties into corporate structures or master funds typically breaks the tax model. Per-property pass-through is the cleanest structure for both investors and the IRS.

The per-property operational stack

Given that every tokenized property requires its own entity, the per-property operational stack becomes the central economic question. The following components are required, at minimum, for every tokenized property:

- **Entity formation and maintenance** — Wyoming or Delaware LLC or DST formation, registered agent fees, annual filings, beneficial ownership reporting under the Corporate Transparency Act. Typical cost: \$1,500 to \$3,500 in year one, \$800 to \$1,500 annually.
- **Securities registration and compliance** — Form D filing with the SEC, state blue-sky filings in each state where investors reside, ongoing accreditation verification, investor onboarding documentation. Typical cost: \$2,000 to \$5,000 in year one, \$1,000 to \$2,500 annually.
- **Transfer agent and recordkeeping** — Maintenance of the official cap table, processing of transfers (including secondary market transfers that change ownership), beneficial ownership tracking. Typical cost: \$2,000 to \$4,000 annually.
- **Custody and wallet infrastructure** — Qualified custody for the tokens themselves, key management, multi-signature controls, security audits. Typical cost: \$1,500 to \$3,000 annually.
- **Distribution mechanics** — Quarterly or monthly distribution calculations, tax withholding for foreign investors (FIRPTA where applicable), distribution payment processing, reconciliation. Typical cost: \$1,500 to \$3,000 annually.
- **Tax filings** — Federal K-1 generation for each investor, state K-1s where required, partnership return preparation (Form 1065), foreign investor withholding documentation. Typical cost: \$3,000 to \$8,000 annually, scaling with investor count.
- **Audit support** — Annual financial statement preparation, audit coordination, supporting documentation. Required for many institutional investors; recommended even where not strictly required. Typical cost: \$4,000 to \$10,000 annually.
- **Securities counsel review** — Ongoing legal review of platform communications, marketing materials, exemption maintenance, regulatory developments. Typical cost: \$2,000 to \$5,000 annually.

Aggregated, the per-property annual operational cost runs approximately \$15,000 to \$40,000, with the wider range reflecting investor count, jurisdictional complexity, and audit requirements. These are fixed costs largely independent of property value — a \$300,000 starter home requires substantially the same operational stack as a \$5 million luxury property.

Why the unit economics fail at mass-market

The implications for tokenization business models are stark. Consider a \$400,000 starter home tokenized through a YieldDeed pledge structure. At industry-standard fee levels — 1.5% origination on the pledged equity, 1.1% annual asset management — the platform generates approximately \$7,000 in year-one revenue against \$20,000 to \$30,000 in fixed operational costs. The unit economics are negative without subsidy. Most tokenization platforms that have launched mass-market residential products have failed at this math, including the more well-funded predecessors of the current generation.

A \$5 million luxury home, by contrast, generates approximately \$65,000 in year-one revenue against the same fixed cost base — comfortably positive on a per-property basis. A \$50 million ground-up

development project generates several hundred thousand dollars in origination fees against a similar fixed cost base. The unit economics scale cleanly upward with property value.

The market is therefore segmented not by demographics or geography but by the property value at which the per-property fixed cost amortizes. The break-even threshold determines the addressable market for a tokenization platform until either regulatory simplification reduces the fixed cost base (post-CLARITY Act, in our analysis) or technology reduces the variable cost of operating the stack (the AI accounting and compliance layer described in Section 4). DeedRiver's strategic position is to serve the segment that works today — development projects and luxury homes — while building the technology stack that brings the unit economics into viability at mass-market scale as regulatory clarity matures.

The break-even property value is not a marketing decision. It is a function of fixed operational costs that, today, sit between \$15,000 and \$40,000 per property per year.

S E C T I O N 4

The AI Accounting & Compliance Layer

Section 3 established that the per-property operational stack is the central economic constraint on tokenization platforms. Section 4 describes how DeedRiver's AI Intelligence Layer is designed to compress that cost — and why this is the platform's primary technical moat against incumbent tokenization providers.

The architectural premise

Every component of the per-property operational stack — entity maintenance, securities filings, transfer agent operations, distribution mechanics, tax preparation, audit support — is fundamentally a workflow over structured data. Real estate operations generate transactional data: rents received, expenses paid, capital improvements made, distributions issued, ownership transfers executed. Securities operations generate compliance data: investor accreditation status, jurisdiction, ticket size, holding period, exemption qualification. Tax operations generate calculation data: cost basis, depreciation schedules, distribution character, state allocations. When this data is generated and stored on-chain — as it is, natively, in a tokenized real estate platform — the workflows that traditionally consume armies of attorneys, accountants, and compliance officers can be substantially automated by AI agents operating over structured data.

This is the architectural premise. The execution is the AI Intelligence Layer.

What is fully automatable

Several components of the per-property stack are fully automatable with current LLM-agent and structured-data tooling. These include:

- **Distribution calculation and execution** — Given rental income data, expense data, and the cap table, calculating each token-holder's pro rata distribution and executing the payment is deterministic. Smart contracts handle the execution; AI agents handle the reconciliation, edge cases, and exception flagging.
- **K-1 generation** — K-1 preparation is a structured transformation from partnership-level financial data to per-investor allocations. Given a complete general ledger and cap table, the K-1 calculation is algorithmically tractable. Edge cases (mid-year ownership changes, special allocations, guaranteed payments) require careful handling but are well-defined.
- **Form D and state blue-sky filings** — These are structured filings with deterministic input requirements. Generating the filings from platform data is a template-population task with regulatory rule-checking; AI agents validate against current regulatory requirements before filing.
- **Accreditation verification and ongoing monitoring** — Third-party verification services already automate the initial check. Ongoing monitoring — tracking whether an investor's accreditation status has lapsed, whether their holdings remain compliant with their accreditation tier — is a continuous-data workflow well suited to agent monitoring.

- **Distribution character classification** — Whether a particular distribution is ordinary income, return of capital, capital gains, or some combination is a function of property-level operating data and cumulative basis tracking. AI agents can maintain this classification continuously across the holding period.
- **Investor communications and reporting** — Quarterly performance reports, year-end summaries, K-1 delivery, regulatory notices. These are templated documents populated from structured data. AI agents handle the generation and delivery.

What requires human review

Other components require human review but are substantially accelerated by AI preparation. These include:

- **Novel tax positions** — 1031 exchange handling, opportunity zone qualification, depreciation method changes, FIRPTA edge cases. AI agents prepare the analysis and supporting documentation; tax counsel reviews.
- **Securities counsel review** — Material platform changes, new product launches, regulatory development responses. AI agents draft and summarize; counsel reviews and signs off.
- **Audit support** — Financial statement preparation, auditor inquiries, supporting documentation. AI agents maintain audit-ready records continuously; the year-end audit becomes a review rather than a reconstruction.
- **Disputes and exception handling** — Investor disputes, contested transfers, regulatory inquiries. AI agents triage and prepare responses; human teams handle resolution.

The unit-economics implications

The economic implication of substantially automating the structured-data components of the per-property stack is that the variable cost per property collapses while the fixed cost of the AI infrastructure remains constant. A platform that has invested in the AI accounting layer can operate a tenth property, a thousandth property, or a millionth property at marginal cost approaching zero for the structured-data workflows.

Concretely, the projected per-property annual operational cost on the DeedRiver platform — once the AI Intelligence Layer is at production scale — is estimated at \$4,000 to \$8,000, compared to the \$15,000 to \$40,000 industry standard described in Section 3. This compression brings the break-even property value for YieldDeed from approximately \$5 million today to approximately \$500,000 to \$800,000 in the post-automation environment. That is the difference between serving the top 5% of homeowners and serving the top 50%.

The AI accounting layer turns the per-property cost from a fixed friction into a variable cost approaching zero. This is the difference between serving the top 5% of homeowners and serving the top 50%.

The data corpus advantage

Beyond cost compression, the AI Intelligence Layer creates a data corpus that compounds in value over time. Every tokenized property on the platform generates structured operational data — rents, expenses, distributions, ownership transfers, tax calculations, compliance filings — that improves the platform's models for the next property. Default prediction, valuation accuracy, distribution forecasting, regulatory edge-case handling: each of these improves with corpus scale. A platform with 10,000 tokenized properties operating for three years has a fundamentally better underwriting and operational engine than a platform with 100 properties operating for six months. This is the network-effects equivalent for tokenization platforms — not a social network effect, but a data network effect.

The corpus advantage also creates strategic optionality. A mature data corpus is valuable not just for DeedRiver's own operations but as a productized data and analytics service for the broader real estate tokenization industry — institutional underwriters, ratings agencies, regulators, secondary market makers. This is one path toward the platform-of-platforms positioning described in Section 5's Phase 4.

S E C T I O N 5

Go-to-Market Strategy

DeedRiver's go-to-market is structured as two parallel motions: supply-side origination of real estate assets onto the platform, and demand-side development of the investor capital base. Each motion has its own phasing, regulatory gates, and unit-economic thresholds. The phases below are calibrated to operational reality, not to opportunity-sizing fantasy.

Supply side: where the assets come from

Phase 1 (Years 1–2): Foundation — Wyoming pilot

The Phase 1 supply-side focus is two segments with viable unit economics today: ground-up development projects in the \$10 million to \$100 million gross development value range, and luxury homes via the YieldDeed wedge application. Both segments share three attributes that make them viable for tokenization today: per-property economics that absorb the operational stack costs described in Section 3, existing SPV structures (development LLCs for projects; new SPVs for luxury YieldDeed), and accredited-only customer profiles that simplify the regulatory burden. Phase 1 operations are based in Wyoming, with selective expansion to cooperative U.S. states (Florida, Texas, Nevada, Colorado) for luxury home origination.

The Phase 1 year-two target is twenty to thirty properties on platform, with \$50 million to \$100 million in tokenized AUM. Current Phase 1 pipeline includes six properties with \$7.1 million in identified value, with the platform infrastructure operational and the first issuances in flight.

Phase 2 (Years 2–3): International expansion and corporate-portfolio dialogue

Phase 2 expands supply-side origination along two vectors. First, international development projects through partner-jurisdiction SPV structures — the same operational pattern as U.S. development tokenization, executed in jurisdictions with operational tokenization frameworks (United Arab Emirates via VARA, Malaysia, the European Union via MiCA passporting, Hong Kong via the SFC framework). An active LOI is in place with a Kuala Lumpur development partner, which will serve as the proof point for the international supply motion. Second, early conversations with institutional single-family rental portfolio operators — the so-called Wall Street landlord segment — about portfolio-scale tokenization conversions. These conversations are exploratory in Phase 2 and become operational in Phase 3.

Phase 3 (Years 3–4): Institutional single-family portfolios

Phase 3 supply-side expansion centers on institutional single-family portfolios. The category — institutional landlords holding single-family rental homes at portfolio scale — comprises an estimated \$50 billion-plus directly held assets across a small number of large operators. These operators face a structural problem that DeedRiver's platform is well-positioned to address: they have built portfolios on debt that is now refinancing at high rates, they want to deleverage without forced selling that would crash markets and trigger capital gains, and they need a structured liquidity mechanism that preserves operational control of the underlying properties.

Tokenized portfolio equity — using the YieldDeed structure adapted to corporate-portfolio scale — provides exactly this mechanism. One enterprise customer relationship in this segment unlocks potentially thousands of properties at once, with unit economics that scale far beyond the individual-homeowner case. The enterprise sales cycle is six to nine months but produces materially larger AUM increments than individual customer acquisition. Phase 3 is therefore the inflection where DeedRiver's AUM growth curve compounds beyond linear individual-property origination.

Phase 3 also coincides with the maturity of the AI Intelligence Layer — described in Section 4 — to production scale, and with the expected post-CLARITY Act regulatory environment. The combination of regulatory clarity, automation-driven cost compression, and corporate-portfolio scale creates the conditions for individual-homeowner YieldDeed at sub-luxury price points to become unit-economic viable as a Phase 3 or Phase 4 expansion.

Phase 4 (Year 4+): Platform-of-Platforms

Phase 4 represents the platform's mature position. DeedRiver operates as the underlying tokenization infrastructure for third-party operators, regulated funds, regional developers, and RIA platforms — white-label deployments where the DeedRiver Asset, Intelligence, and Liquidity Layers serve as the operational backbone for institutional issuers. The asset class expands beyond residential and development into commercial office, industrial, hospitality, and infrastructure as institutional comfort with on-chain real estate exposure matures. Multi-jurisdiction licensure is complete; international expansion is structurally embedded; the AI accounting and compliance layer is a productized service in its own right.

Demand side: where the capital comes from

Phase 1 (Years 1-2): Accredited US investors via Reg D 506(c)

The Phase 1 demand-side focus is accredited domestic investors qualifying under Reg D 506(c). The regulatory framework permits general solicitation, which is critical for platform marketing. Investor acquisition channels include registered investment advisor (RIA) partnerships, family office networks, high-net-worth crypto-native investor communities, and content marketing targeting accredited audiences. Average ticket size targets are \$25,000 to \$500,000 per investor. The Phase 1 demand pool is seeded internally by the DeedRiver Capital fund, which provides initial liquidity for YieldDeed pledges before external investor capital scales.

Phase 2 (Years 2-3): Reg A+ retail unlock

Phase 2 demand-side expansion follows Reg A+ Tier 2 qualification. Reg A+ Tier 2 permits annual raises of up to \$75 million from non-accredited investors with general solicitation, with the regulatory burden falling between Reg D 506(c) and full S-1 registration. The SEC review process typically takes twelve to eighteen months, which is initiated in Phase 1 and completed in Phase 2. Minimum investment thresholds drop to the \$100 to \$1,000 range, enabling mass-affluent retail participation. Acquisition channels expand to include direct-to-consumer marketing, fintech partnerships, and neobank integrations.

Phase 3 (Years 3-4): Institutional and international capital

Phase 3 demand-side expansion targets institutional allocators — pension funds, insurance companies, endowments, family offices, sovereign wealth funds, and large RIA platforms. The operational

requirements are substantially different from accredited or retail flow: ATS-grade secondary liquidity, institutional custody integration (BNY Mellon, State Street, or equivalent), audited GAAP financial reporting, and a multi-year track record. The Phase 3 institutional pool requires the demonstrated scale and operational maturity that Phase 1 and Phase 2 generate. International capital expansion runs in parallel via partner-jurisdiction frameworks (VARA, MiCA, MAS Project Guardian, SFC).

Phase 4 (Year 4+): DEX platform liquidity at scale

Phase 4 sees the DEX Marketplace operating at scale as the primary liquidity venue for tokenized real estate, with sub-1.5% fees per side, real-time price discovery, and compliant cross-border token transfer. The platform-level liquidity at this stage enables continuous secondary trading, market-making across token classes, and structured products built on top of the underlying tokenized assets.

The strategic logic of the phasing

Each phase is gated by a specific operational or regulatory event, not by a calendar date. Phase 1 is viable today because Reg D 506(c) is operational, Wyoming statutes are operational, and luxury and development unit economics work at current operational costs. Phase 2 requires one international deal closed and Reg A+ qualification initiated. Phase 3 requires CLARITY Act final passage (or equivalent state-level frameworks), the AI accounting layer at production scale, and demonstrated enterprise sales capability. Phase 4 requires institutional infrastructure operational and multi-jurisdiction licensure complete.

The phasing is also designed to be honest about the limits of seed-stage planning. Phase 1 is what the seed capital funds. Phase 2 is what the seed-to-Series-A bridge funds. Phases 3 and 4 are the institutional-round and growth-stage chapters that follow. A pitch deck that claims Phase 4 commitments at the seed stage is overpromising. A pitch deck that omits Phase 4 underprices the platform's terminal value. The honest position is that Phase 1 is funded execution, Phase 2 is a credible near-term plan, and Phases 3 and 4 are the structural endgame that justifies the platform's strategic positioning.

AI-driven accounting automation makes per-property unit economics work at any scale.

Competitive Landscape

DeedRiver competes in two distinct categories that are often conflated by external observers but represent fundamentally different operational models and competitive dynamics. The first category is consumer financial products against which YieldDeed is positioned — home equity lines of credit, reverse mortgages, home equity investment agreements, and real estate investment trusts. The second category is tokenization platform infrastructure against which the broader DeedRiver platform competes — Securitize, Tokeny, Polymath, Centrifuge, and a small number of other providers. The competitive analysis below addresses both.

Versus consumer financial products

YieldDeed is positioned as an alternative to traditional consumer financial products for homeowners seeking liquidity against home equity. The competitive comparison below focuses on the structural properties that matter to homeowners considering alternatives to HELOCs, reverse mortgages, home equity investment agreements (HEAs), and REIT exposure.

Property	HELOC	Rev. Mtg.	HEA	REIT	DeedRiver
No monthly payment	—	✓	✓	✓	✓
Non-recourse	—	✓	Partial	✓	✓
Deed retained	✓	✓	✓	n/a	✓
No appreciation give-up	✓	—	—	n/a	✓
Fractional liquidity	—	—	—	Limited	✓
Secondary market	—	—	—	—	✓
Sub-1.5% fees	—	—	—	—	✓
Integrated back-office accounting	—	—	—	—	✓

The structural differentiation is widest in the bottom four rows. HELOCs, reverse mortgages, HEAs, and REITs all serve narrower configurations of the homeowner liquidity problem. None unifies non-recourse pledge mechanics, fractional liquidity, secondary market access, sub-1.5% fees, and integrated back-office accounting into a single product. The last row is the clearest categorical differentiation: integrated back-office accounting is outside the product scope of consumer financial products entirely. It is a capability that exists only when the platform itself is built on tokenization-native architecture, with on-chain operational data as the substrate for AI-driven automation.

Versus tokenization platforms

The second competitive category is the existing tokenization platform infrastructure — providers that offer token issuance, smart contract deployment, and (in some cases) secondary trading capabilities for security tokens. The major incumbents include Securitize, Tokeny, Polymath, Centrifuge, and a small number of smaller providers. These platforms are technology layers: they provide the on-chain rails but leave the operational stack — entity formation, securities filings, distribution mechanics, tax preparation, audit support — to the issuer or to a network of external service providers.

DeedRiver's competitive position against these platforms rests on the integration of the operational stack with the technology stack. The closest analogy is the difference between a payment processor and a full-service neobank. Stripe handles payment rails; a neobank handles rails plus accounting plus treasury plus compliance plus customer support. The neobank has higher per-customer take rates, stickier customers, and deeper moats — at the cost of operational complexity that the payment processor avoids.

Securitize, the largest tokenization platform by tokenized assets under management, has built a strong position in the institutional Treasury tokenization market through its relationships with BlackRock, Apollo, Hamilton Lane, and other institutional issuers. Securitize's market position in private market tokenization is substantial and likely to remain so. However, Securitize's product model is the technology-layer model: it provides the issuance and transfer infrastructure but does not handle the operational stack for the issuer. For institutional issuers (BlackRock, Apollo) this division of labor is appropriate — the institutions handle the operational stack themselves. For mid-market issuers and individual property tokenization, the technology-layer model leaves the issuer to navigate the operational stack alone, which is a structural barrier to adoption.

DeedRiver's platform-plus-operational-stack model is therefore not competing directly with Securitize for institutional Treasury tokenization. It is competing for the segment that Securitize's model does not serve well — real estate-specific issuers, mid-market property tokenization, and the long tail of properties that require integrated operational support to be unit-economic viable. This is a substantial addressable segment and one where the competitive dynamics favor the integrated model.

Regulatory Foundation

DeedRiver operates within a regulatory framework that combines U.S. federal securities law, Wyoming state digital asset statutes, and — for international expansion — partner-jurisdiction regulatory frameworks. The regulatory environment is evolving rapidly in 2026, with several major federal initiatives in late-stage legislative progress. This section summarizes the operative regulatory framework, the planned regulatory progression, and the international regulatory landscape.

United States: federal framework

DeedRiver's U.S. operations are structured under Reg D 506(c), the SEC exemption that permits general solicitation of accredited investors. This exemption is the operational foundation for Phase 1 of the platform's go-to-market. Reg A+ Tier 2 qualification — which permits annual raises of up to \$75 million from non-accredited investors with general solicitation — is the planned Phase 2 expansion, with the SEC review process initiated in Phase 1 and qualification expected in Phase 2.

The CLARITY Act — the Digital Asset Market Clarity Act of 2025 — cleared the Senate Banking Committee 15-9 on May 14, 2026. The Act establishes jurisdictional clarity between the SEC and the CFTC for digital assets, provides safe harbor provisions for compliant tokenization platforms, and codifies the regulatory treatment of decentralized exchange protocols. Final Senate passage is plausible by late summer 2026, with full enactment realistic by year-end 2026. The CLARITY Act is the most significant U.S. legislative development for tokenization in over a decade and is the regulatory inflection point assumed in Phase 3 of the DeedRiver go-to-market.

The GENIUS Act, signed into law in July 2025, became the first federal stablecoin framework. While stablecoin regulation is not directly central to real estate tokenization, the framework provides the regulated payments rail for tokenized asset settlement and distribution. The Act's passage signals federal regulatory engagement with digital asset infrastructure beyond enforcement-only postures, which is favorable for the broader tokenization category.

Wyoming: the U.S. operational home

Wyoming's digital asset statutes provide the strongest tokenization-favorable regulatory framework among U.S. states. The Wyoming DAO LLC framework, enacted in 2021, was the first U.S. state law to explicitly recognize the legal personhood of decentralized autonomous organizations and to provide a registered-entity structure for token-issuing organizations. Subsequent statutes have addressed digital asset custody (the Special Purpose Depository Institution charter), tokenized property rights, and the legal recognition of smart contract-mediated transactions.

Wyoming's regulatory clarity, combined with its low corporate tax environment and operational efficiency, makes it the natural operational home for tokenization-native platforms in the United States. DeedRiver is incorporated in Wyoming for these reasons; the platform's initial property pilots are based in Wyoming; and the company maintains active relationships with Wyoming regulatory counsel and the Wyoming Blockchain Task Force network.

International: operative frameworks

DeedRiver's international expansion is built around partner-jurisdiction regulatory frameworks that are operational today and that support real estate tokenization explicitly. The principal jurisdictions are summarized below.

- **European Union (MiCA)** — The Markets in Crypto-Assets Regulation has been fully applicable since December 30, 2024. Over ninety crypto-asset service providers have been authorized under the framework. MiCA provides passportable regulatory recognition across EU member states, enabling efficient pan-EU operations for compliant tokenization platforms.
- **United Arab Emirates (VARA)** — Dubai's Virtual Assets Regulatory Authority has been operational since 2023. Dubai's Land Department launched the region's first real estate tokenization pilot in 2024, with a stated target of \$16 billion in tokenized real estate by 2033. The UAE represents one of the most active institutional tokenization markets globally.
- **Hong Kong (SFC, HKMA)** — Hong Kong published a ten-year RWA tokenization roadmap in 2025. The Stablecoins Ordinance became effective August 1, 2025, and Project Ensemble — the HKMA's wholesale tokenization sandbox — is operational with institutional participants. The first institutional real estate bonds on Canton Network launched from Hong Kong in September 2025.
- **Singapore (MAS Project Guardian)** — Project Guardian brings together UBS, Invesco, Apollo, and other institutional participants on tokenized asset pilots. Singapore is positioned as Asia's institutional tokenization hub alongside Hong Kong.
- **Malaysia (SC, Labuan IBFC)** — Securities Commission Malaysia has an operational Recognized Market Operator framework for digital asset exchanges. Labuan IBFC provides offshore-financial-center structures for international investor access. An active DeedRiver LOI is in place with a Kuala Lumpur development partner.

Team & Execution

DeedRiver is led by founders whose combined experience covers the institutional finance, technology infrastructure, and capital formation capabilities required to execute the platform thesis. The team's composition is unusual for a seed-stage tokenization company: the technical leadership has already scaled an institutional fund platform from zero to \$5 billion in assets under management, and the company is being built with that operational discipline from day one.

Iosif Ziman, PhD — Co-Founder & Chief Technology Officer

Dr. Iosif Ziman is the former Chief Technology Officer of BFAM Partners, the Hong Kong-based institutional hedge fund. Under Dr. Ziman's technology leadership, BFAM scaled from zero to a peak of \$5 billion in assets under management, with 25%+ returns across five consecutive years. He architected the trading infrastructure, fund operations technology, and institutional-grade compliance systems that supported the fund's growth from launch through institutional scale. The technology stack he built at BFAM is directly analogous to what DeedRiver is now building for tokenized real estate: institutional-grade operational infrastructure that handles regulatory complexity, multi-jurisdiction operations, and the kinds of high-frequency reconciliation and reporting workflows that determine whether a fund or platform can operate at scale.

Dr. Ziman holds a PhD and has spent his career at the intersection of institutional finance and technology infrastructure. His network in the Asian institutional and family-office capital base is a strategic asset for DeedRiver's international expansion.

Joseph — Co-Founder & Chief Executive Officer

Joseph is a multi-time founder with deep experience in product strategy, capital formation, and platform development. He led the structuring of DeedRiver's pilot, including the Wyoming regulatory framework, the Reg D 506(c) compliance architecture, and the initial property origination pipeline. Joseph's prior operational and concept design experience, including engagement with Dragone Entertainment, brings a distinctive aesthetic and strategic sensibility to the company's product and brand presentation.

Why this team

Tokenized real estate is not, fundamentally, a blockchain problem. It is an institutional operations problem that happens to use blockchain as the substrate. The companies that have failed in this category — and there have been many — have generally been technology-led, with founders who understood smart contracts deeply but underestimated the operational complexity of regulated securities, multi-jurisdiction compliance, and institutional-grade fund operations. The companies that have succeeded in adjacent categories — Figure in HELOC tokenization, Securitize in institutional Treasury tokenization — have been led by founders with deep institutional finance backgrounds who layered the blockchain technology on top of mastered operational capabilities.

DeedRiver's team composition follows this pattern. The technical leadership has already operationalized institutional-grade fund infrastructure at \$5 billion scale. The product and capital formation leadership

has built and structured multiple ventures. The combination is calibrated to the actual challenge of tokenized real estate rather than to the surface-level blockchain narrative.

The company has engaged securities counsel for the Wyoming pilot and ongoing regulatory work, has validated the Wyoming entity structure with experienced counsel, and is developing the custody partner pipeline necessary for institutional-grade operations. The seed round is structured to fund the platform through the Phase 1 supply-side execution described in Section 5, with the resulting traction expected to inform a Series A round that funds Phase 2 international expansion and Phase 3 enterprise sales.

Tokenized real estate is not a blockchain problem. It is an institutional operations problem that happens to use blockchain as the substrate.

Conclusion: The Acquisition Thesis

This whitepaper has detailed the operational reality of tokenized real estate, the architecture of the DeedRiver platform, the AI-driven cost compression that makes per-property unit economics viable at any scale, the phased go-to-market that begins with development projects and luxury homes today, the competitive landscape across both consumer financial products and tokenization platforms, the regulatory foundation in Wyoming and internationally, and the team that has the operational background to execute. This concluding section addresses the strategic endgame: the acquisition thesis that frames DeedRiver's terminal value.

Real estate tokenization is a category in which first-mover advantage compounds through a specific set of mechanisms. Property origination is relationship-driven and difficult to replicate quickly — developer relationships, luxury homeowner trust, corporate-portfolio enterprise sales — each takes months to years to build. Operational data corpus, as described in Section 4, compounds with each property and creates network-effects-like advantages for the platform that accumulates the largest corpus first. Regulatory licensure and jurisdiction-specific compliance architecture take years to assemble and cannot be acquired off the shelf. Institutional customer relationships, once established at scale, are sticky for the same reasons that traditional financial institutional relationships are sticky: switching costs are high and the value of continuity is meaningful.

These dynamics create a category that, once it matures, will be concentrated. The current diffuse landscape of small tokenization platforms, each addressing a niche of the market, is the transitional state before institutional consolidation. The institutional players — BlackRock, JPMorgan, Goldman Sachs, Apollo, KKR, and their counterparts — are already on-chain in adjacent categories (Treasuries, private credit, money-market funds). Their move into real estate tokenization is a matter of when, not if. The 18-30 month window between today and that institutional move is the strategic capture period.

History suggests these institutions are more likely to acquire established platforms in mature categories than to build from scratch. Goldman's history of acquiring trading infrastructure, JPMorgan's acquisitions in digital asset and tokenization, BlackRock's strategic positioning through partnerships and minority stakes — these are the patterns. The early movers in regulated tokenization infrastructure who establish category leadership during the 18-30 month window become the natural acquisition targets when the category matures.

There is also a less-discussed acquirer category: the customers themselves. The institutional single-family operators described in Section 5's Phase 3 — the Wall Street landlords with portfolios at scale — have strong incentives to own the tokenization rail their portfolios use, rather than rent it from a third party. Strategic acquisition by a customer is a different exit pathway than acquisition by a Wall Street institution, but the dynamics that make it attractive are the same: high switching costs, sticky operational integration, and strategic value of vertical integration.

The early movers in regulated tokenization infrastructure who establish category leadership during the 18-30 month

window become the natural acquisition targets when the category matures.

DeedRiver is positioned to be one of those early movers. The platform thesis — comprehensive infrastructure across asset, intelligence, and liquidity layers, integrated operational stack, AI-driven cost compression, regulated multi-jurisdiction footprint — is calibrated to the strategic position that makes such acquisitions valuable. The team — institutional fund operations background, multi-time founder, regulatory and capital formation depth — is calibrated to the execution required. The seed round funds the Phase 1 traction that establishes the platform's position. The subsequent rounds and the eventual exit are the structural outcome of executing that position through the category's maturation.

DeedRiver

Real estate. Tokenized.
